Formwork Components

The basic element of formwork is the panel which is a combination of extruded aluminium sections, manufactured from a high strength aluminium alloy to very high specifications and very strict tolerances.

The contact face of the panel is a 4mm thick extruded section which is reinforced with specially designed extrusions that act both as a stiffener and for ease of handling. Once welded together it forms a robust component that is lightweight with excellent stiffness to weight ratio, yielding minimal deflections under concrete loading.

Panels are manufactured in standard and non-standard sizes and shapes, produced to the requirements of each and every project. Once produced, they are subjected to a trial assembly at our factory to ensure hassle free installation on site.
